

# On the Persistence of Higher-Order Interactions in Real-World Hypergraphs - Supplementary Document

## A Observations

**A.1 Global Analysis: Persistence vs. Frequency** The distributions of the persistence of HOIs in all 13 real-world hypergraphs are shown in Fig. 1. While the distributions from most datasets clearly obey power-laws, there exist anomalies that deviate from the fitted lines in the distributions from the Eu and Classes datasets. The anomalies from the Eu dataset indicate the surprising abundance of highly persistent HOIs.

## A.2 Local Analysis (1): Group Features vs. Group Persistence.

**Observations.** The mutual information (MI) and Pearson correlation coefficients (CC) between each structural group feature and the persistence in each dataset are shown in Table 1. Most features are positively correlated with persistence, and on average, the CC is strongest for  $\#$ , (i.e., the number of hyperedges containing each HOI  $S$ ), followed by  $\mathcal{H}$  (i.e., the entropy in the sizes of hyperedges containing each HOI  $S$ ), and then  $\Sigma/\cap$ . Notably,  $\Sigma/\#$  (i.e., the average size of the hyperedges containing each HOI  $S$ ) is the only feature that is negatively correlated with persistence. We show in Fig. 2 the distributions of  $\#$  and  $\Sigma/\#$  of HOIs with each level of persistence in all 13 real-world hypergraphs.

OBSERVATION 1. (GROUP FEATURES VS. GROUP PERSISTENCE) *In real-world hypergraphs, the persistence of each HOI  $S$  is positively correlated with (a) the number of hyperedges containing  $S$  and (b) the entropy in the sizes of hyperedges containing  $S$ .*

## A.3 Local Analysis (2): Node Features vs. Group Persistence

**Node Features.** As described in Section 4.1, for each HOI appearing for the first time at time  $t$ , we consider the hypergraph  $H$  consisting of all hyperedges appearing between time  $t + 1$  and  $t + T_s$ . The structural node features are obtained from the projected graph  $H'$  (see Section 3.1) of  $H$ , as described below. Recall that,  $H'$

is a pairwise graph, and for each node  $v$ , we use  $N'(v)$  to denote the set of its neighbors in  $H'$ . We define the features as follows:

- **Degree ( $d$ ):** The *degree*  $d(v)$  of a node  $v$  is the number of the edges adjacent to  $v$  in  $H'$ .

$$d(v) := |N'(v)|.$$

- **Weighted degree ( $w$ ):** The *weighted degree*  $w(v)$  of a node  $v$  is the sum of the weights of the edges incident to  $v$  in  $H'$ .

$$w(v) := \sum_{u \in N'(v)} \Omega(u, v).$$

- **Number of occurrences ( $o$ ):** The *number of occurrences*  $o(v)$  of a node  $v$  is the number of hyperedges including  $v$  in  $H$ .

$$o(v) := |\{e \in E : v \in e\}|.$$

- **Core number ( $c$ ):** The  *$k$ -core*  $H'_k$  of  $H'$  is its maximal subgraph where every node is adjacent to at least  $k$  nodes in it. The *core number* of a node  $v$  is the largest  $k$  such that  $H'_k$  contains  $v$ .

- **PageRank ( $r$ ):** The PageRank  $r(v)$  of a node  $v$  in  $H'$  is the stationary probability of a random walker on  $H'$  being at  $v$ . At each time, the random walker either follows (with probability  $\beta = 0.85$ ) an incident edge chosen uniformly at random or jumps (with probability  $1 - \beta$ ) to a node chosen uniformly at random.

- **Average degree of neighbors ( $\bar{d}$ ):** We denote the *average degree of the neighbors* of a node  $v$  by  $\bar{d}(v)$ .

$$\bar{d}(v) := \frac{1}{d(v)} \sum_{u \in N'(v)} d(u).$$

- **Average weighted degree of neighbors ( $\bar{w}$ ):** We denote the *average weighted degree of the neighbors* of a node  $v$  by  $\bar{w}(v)$ .

$$\bar{w}(v) := \frac{1}{d(v)} \sum_{u \in N'(v)} w(u).$$

- **Local clustering coefficient ( $l$ ):** The *local clustering coefficient*  $l(v)$  of a node  $v$  is defined as

$$l(v) := \frac{|\{\{u, w\} \in E' : u \in N'(v) \text{ and } w \in N'(v)\}|}{\binom{d(v)}{2}},$$

where the denominator is the number of pairs of the neighbors, and the numerator is the number of such pairs that are directly joined by an edge. That is,  $l(v)$  quantifies how close the neighbors of  $v$  are, and equivalently, their tendency to form a clique together.

**Observations.** The mutual information (MI) and Pearson correlation coefficients (CC) between each structural node feature, which is averaged over the nodes involved in each HOI, and the persistence in each dataset are shown in Table 1. On average, the MI is largest for  $\bar{w}$  (i.e., the average weighted degree of neighbors),  $\bar{d}$  (i.e., the average degree of neighbors), and  $r$  (i.e., PageRank). Notably,  $\bar{w}$  and  $\bar{d}$  are negatively correlated with persistence. In addition to  $r$ ,  $w$  (i.e., weighted degree), and  $o$  (i.e., the number of occurrences) are positively correlated with persistence. The distributions of averaged  $w$  and  $\bar{w}$  of HOIs with each level of persistence in all 13 real-world hypergraphs are shown in Fig. 3.

OBSERVATION 2. (NODE FEATURES VS. GROUP PERSISTENCE) *In real-world hypergraphs, the persistence of each HOI is negatively correlated with the average (weighted) degree of neighbors of each node involved in the HOI.*

OBSERVATION 3. (NODE FEATURES VS. NODE PERSISTENCE) *In real-world hypergraphs, the weighted degree and number of occurrences of each node are positively correlated with the persistence of HOIs that the node is involved in.*

## B Linear Regression Analysis

In Table 2, we report the average coefficient, standard error, and  $p$ -value of each structural feature obtained by linear regression analysis of each dataset. The results are summarized in Table 3.

### A.4 Local Analysis (3): Node Features vs. Node Persistence

**Observations.** We report in Table 1 the mutual information (MI) and Pearson correlation coefficients (CC) between each structural node feature and the  $k$ -node persistence in each dataset. Overall, the MIs are larger than those obtained in the previous subsections. On average, the MI is largest for  $r$  (i.e., PageRank), followed by  $\bar{w}$  (i.e., the average weighted degree of neighbors), and then  $\bar{d}$  (i.e., the average degree of neighbors). The correlation is strongest for  $o$  (i.e., the number of occurrences) and  $w$  (weighted node degree), which are positively correlated with  $k$ -node persistence. Among the features, only  $\bar{w}$ ,  $\bar{d}$ , and  $l$  (i.e., the local clustering coefficient) are negatively correlated with  $k$ -node persistence. The distributions of  $w$  and  $\bar{w}$  of nodes with each level of  $k$ -node persistence in all 13 real-world hypergraphs are shown in Fig. 4.

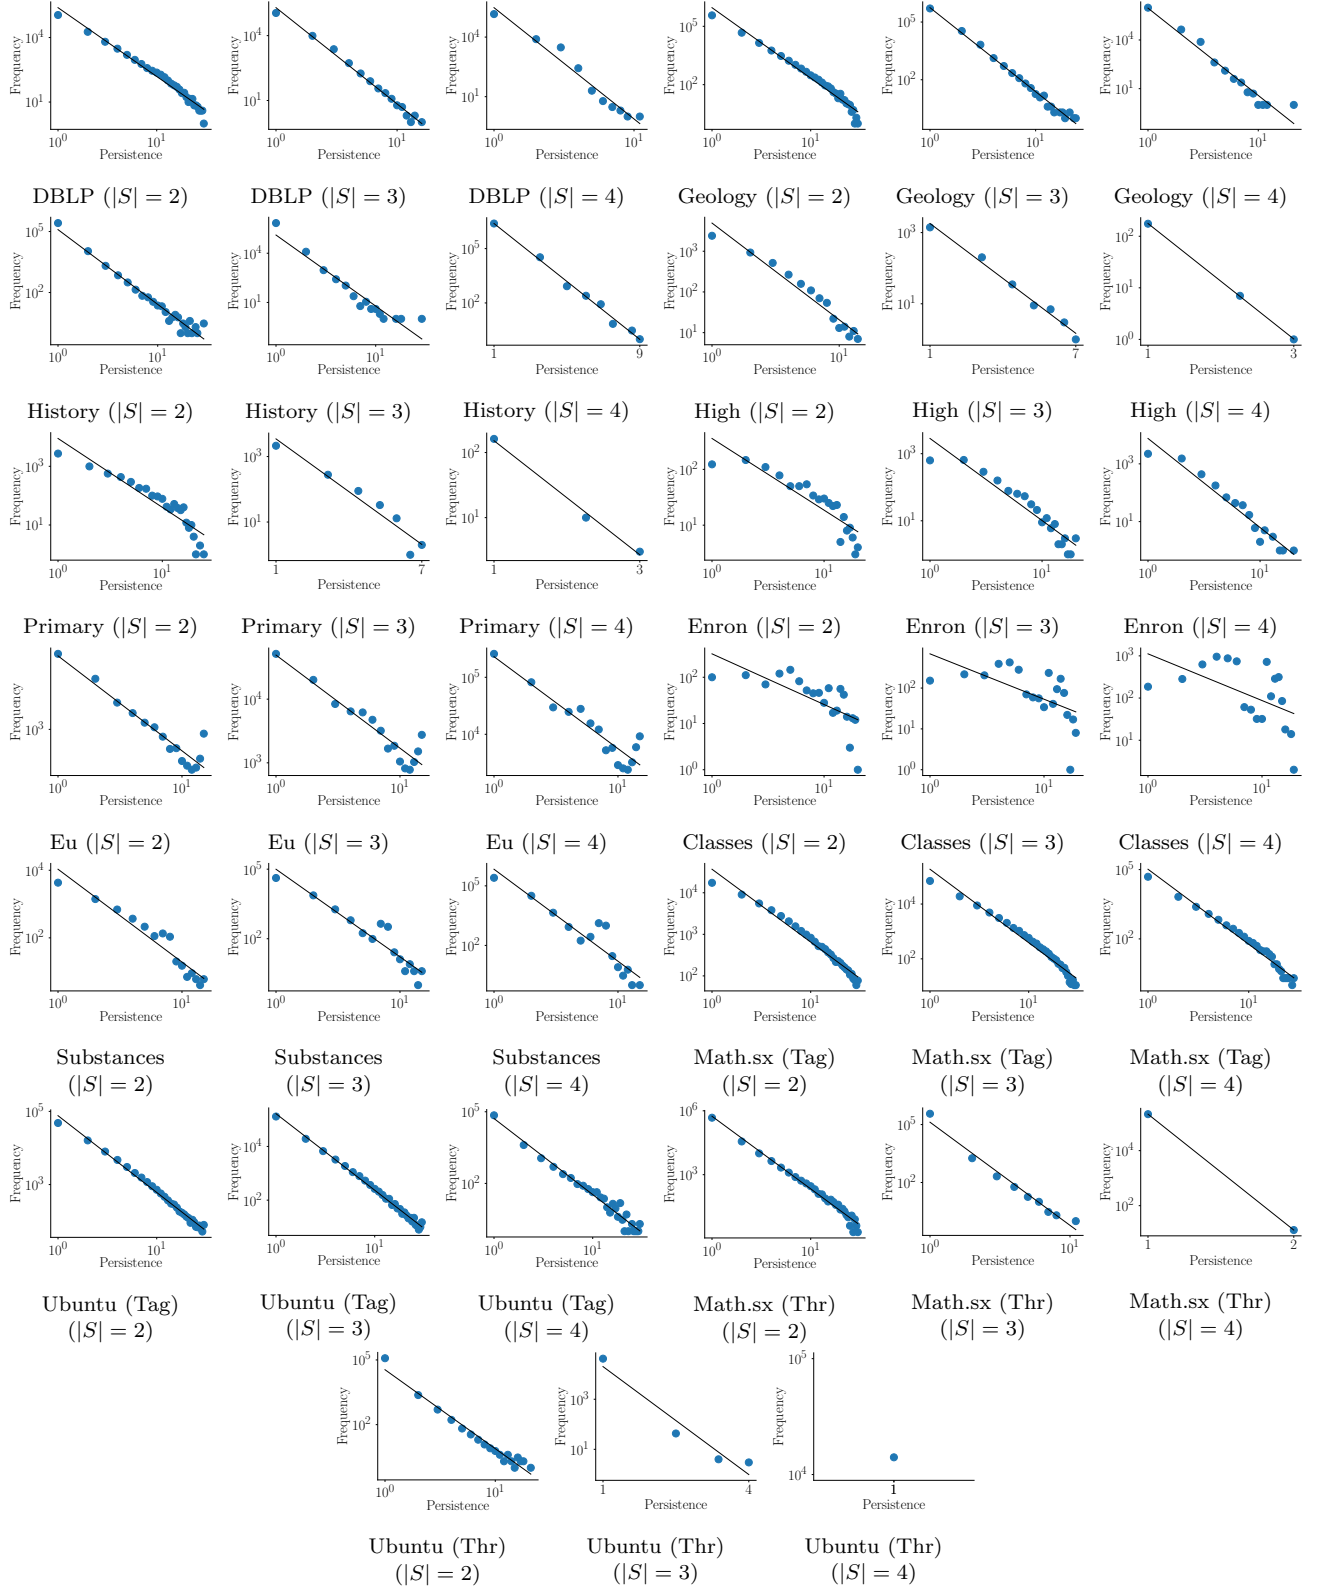

Figure 1: **Power-Laws in the Persistence of HOIs.** Note that there exist some anomalies in the Eu (Email) and Classes (NDC) datasets.

Table 1: **Features vs. Persistence.** Mutual information (MI) and correlation coefficients (CC) in all 13 real-world hypergraphs.

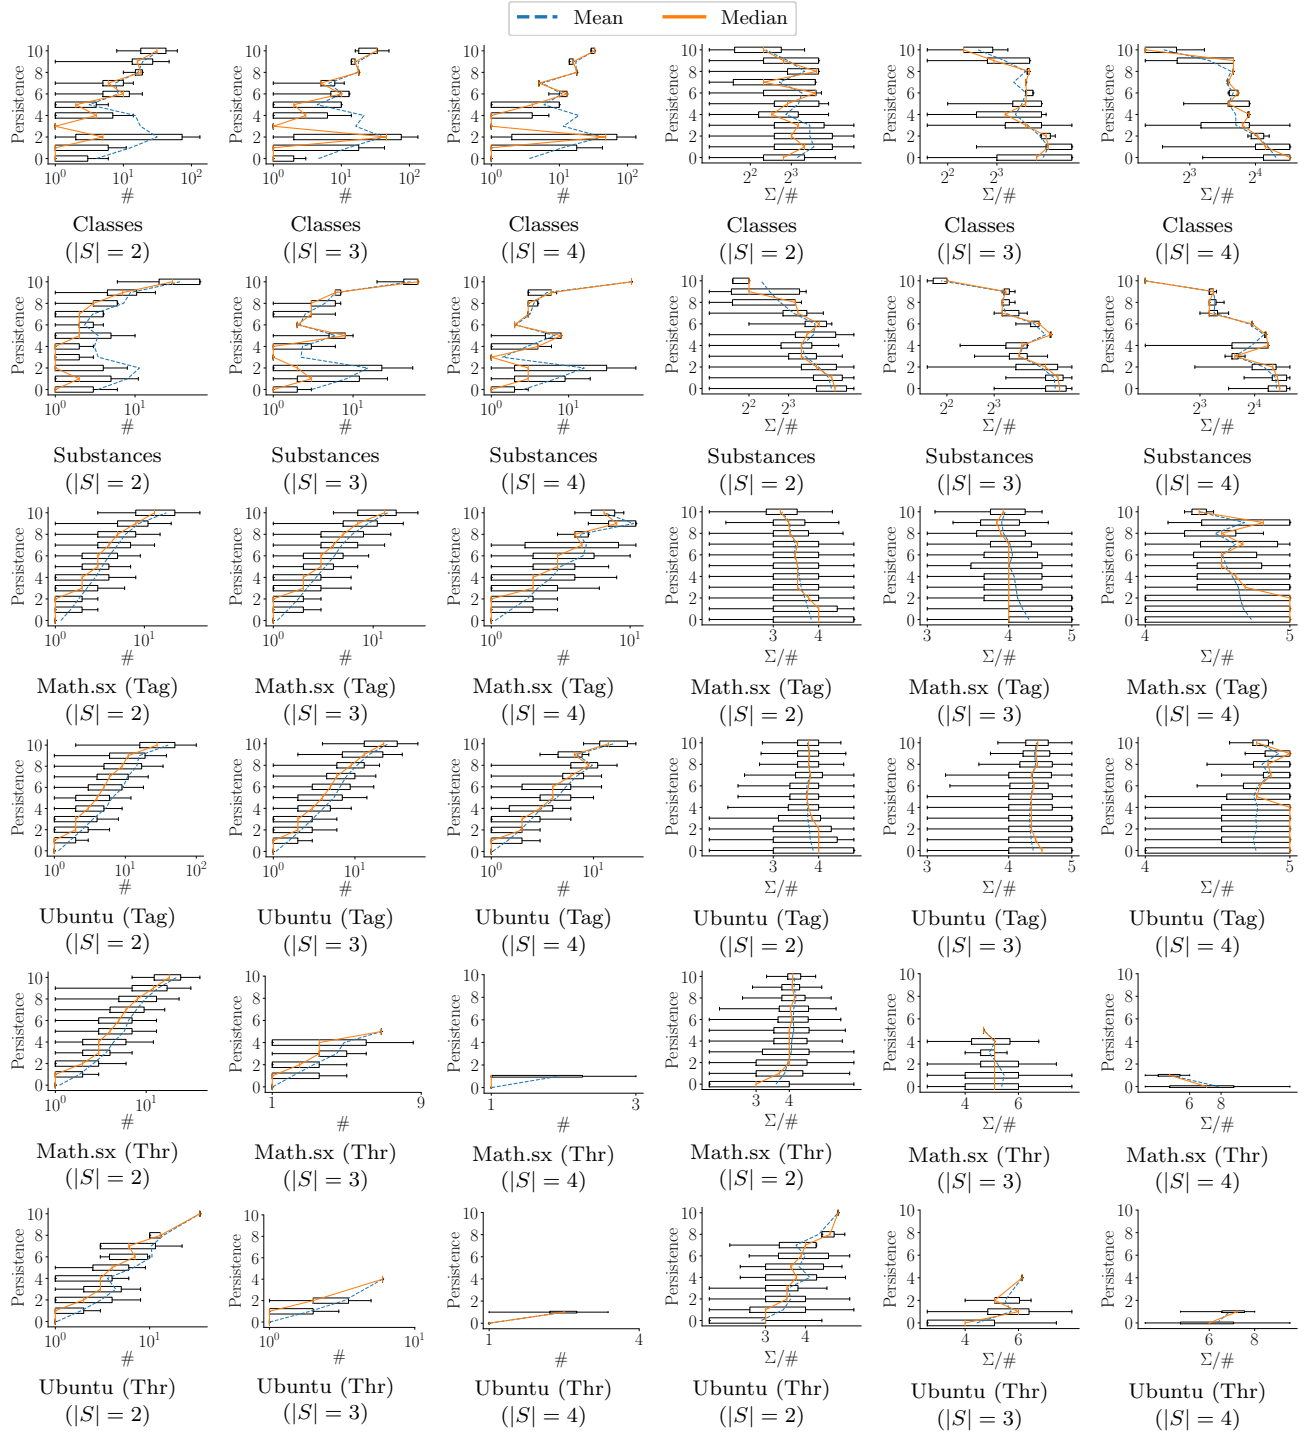

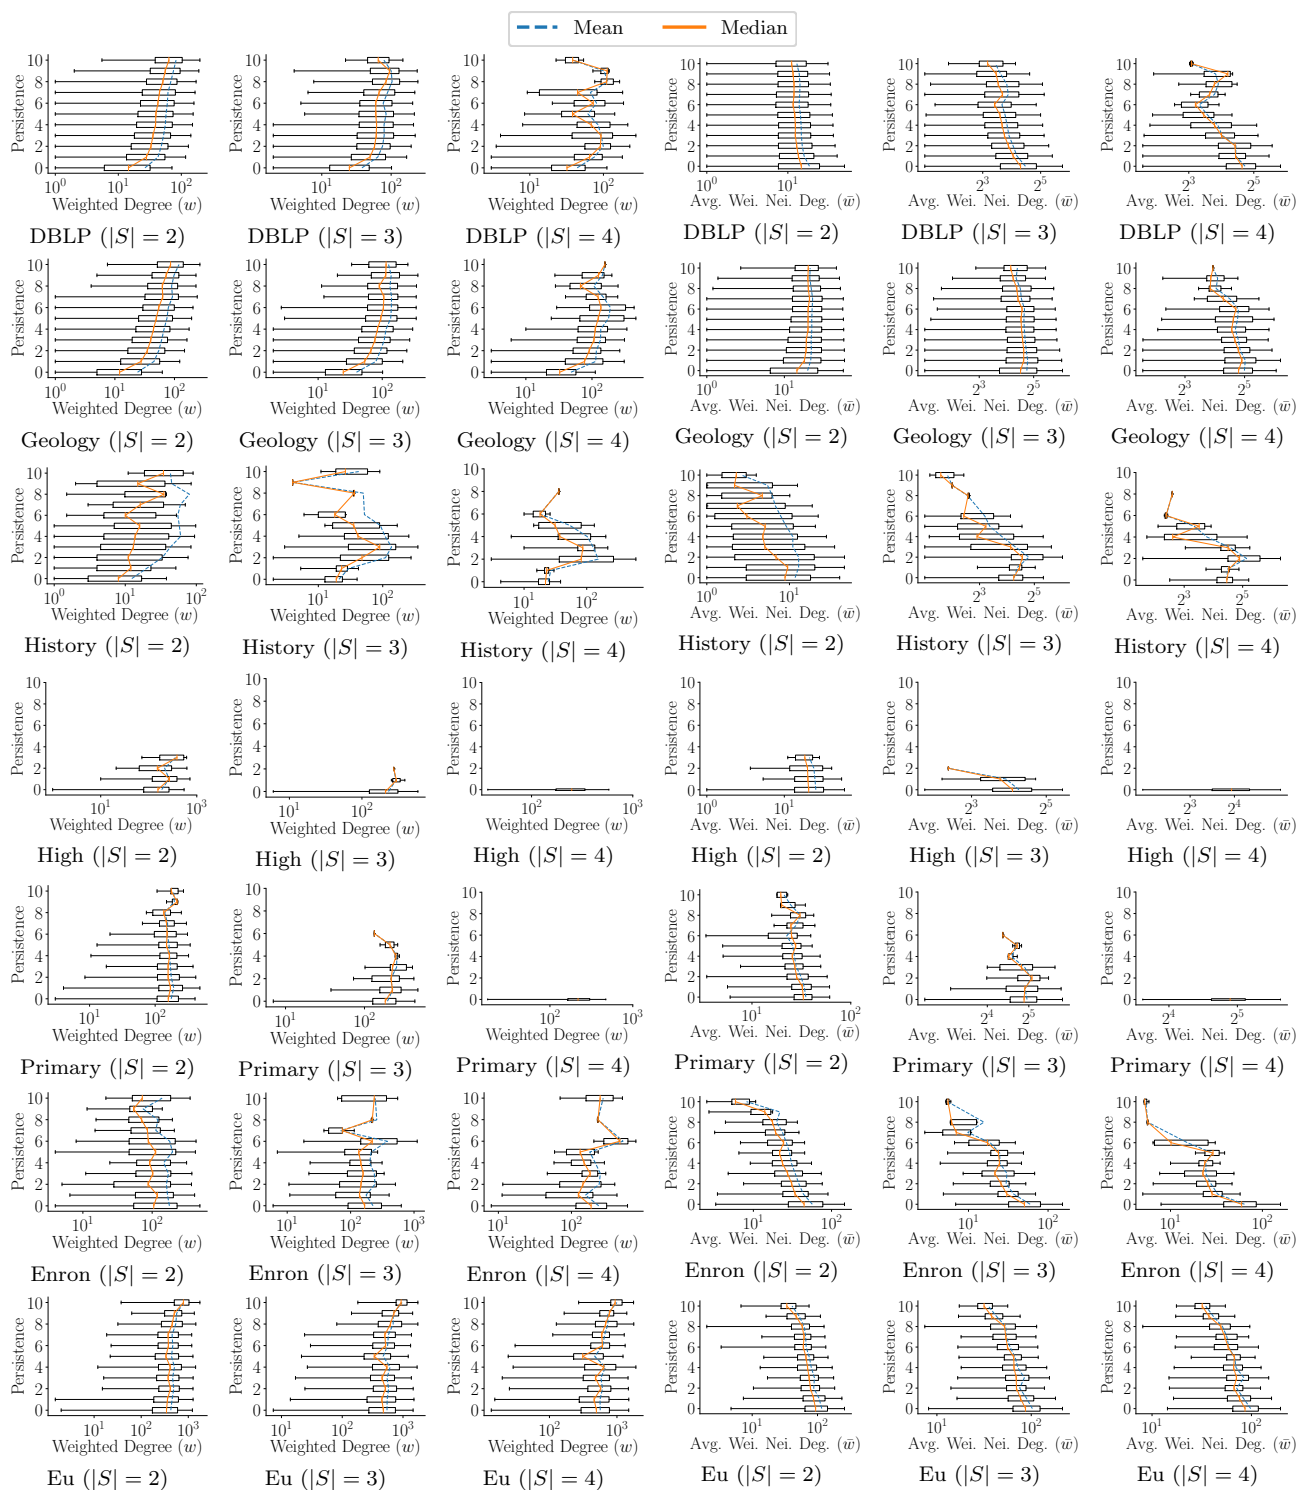

Figure 2: **Group Features vs. Group Persistence.** The distribution of  $\#$  (i.e., the number of hyperedges containing each HOI) and  $\Sigma/\#$  (i.e., the average size of the hyperedges containing each HOI) of HOIs with each level of persistence in all 13 real-world hypergraphs.

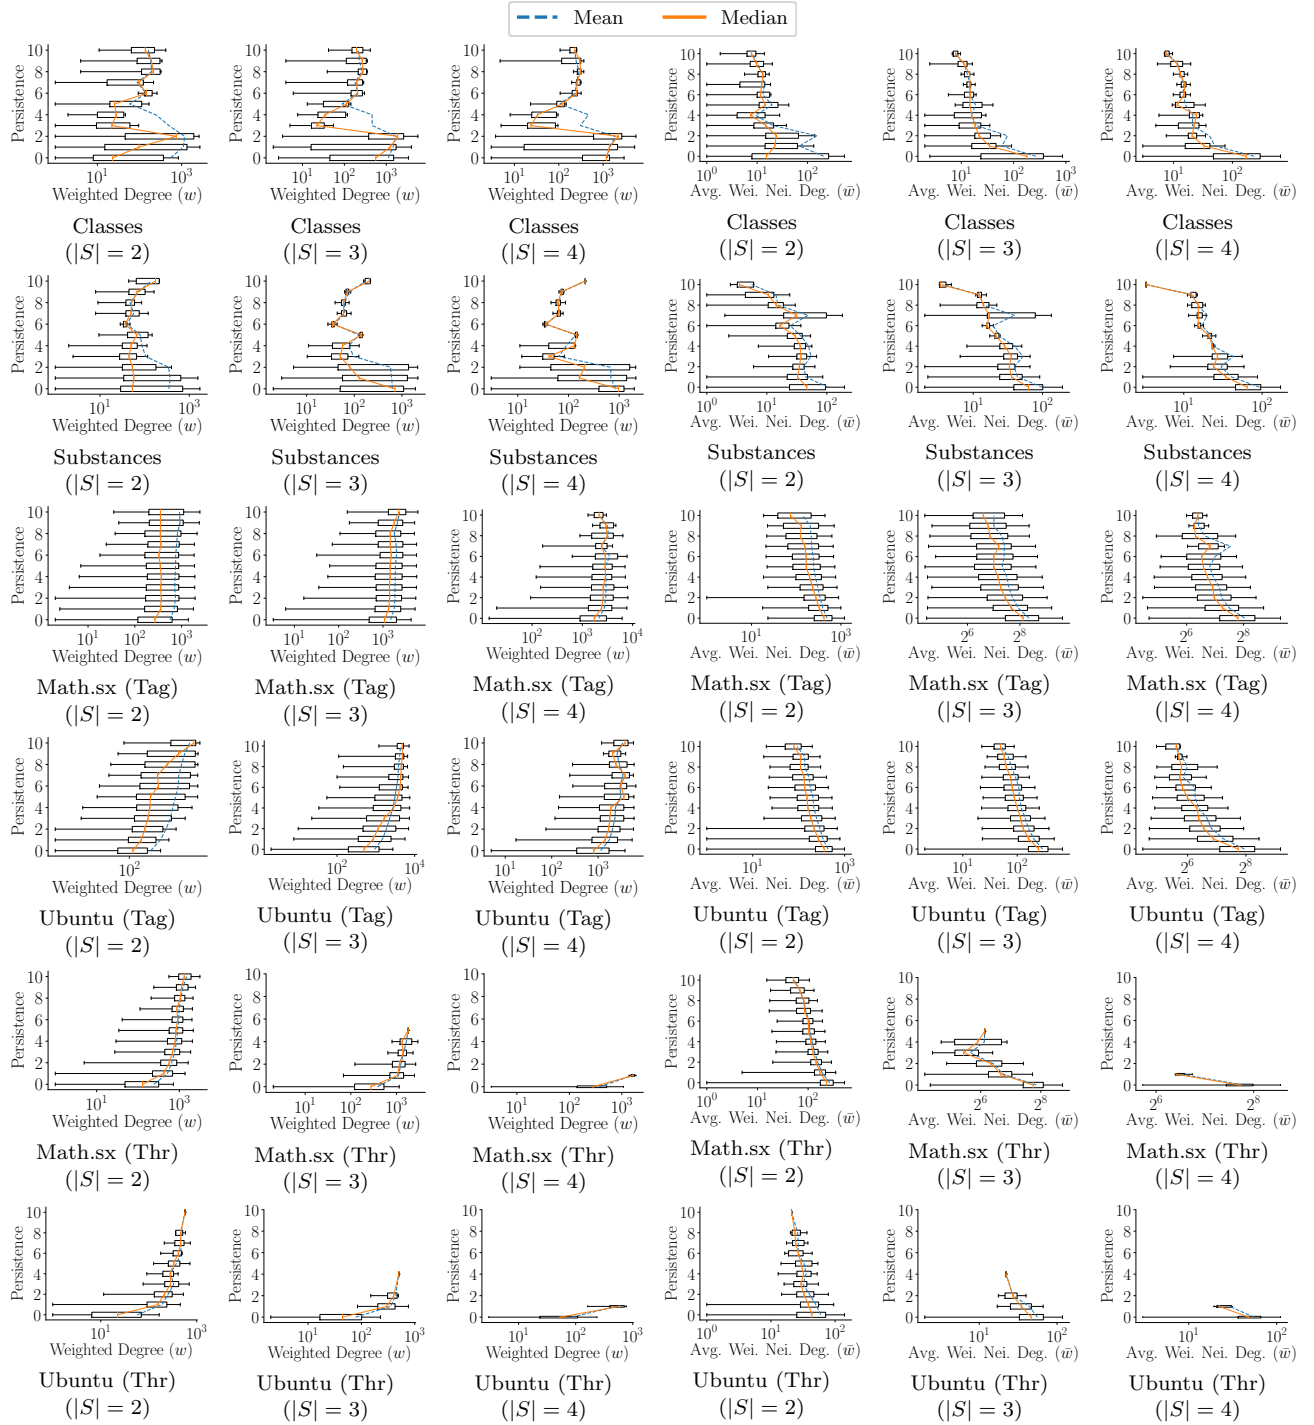

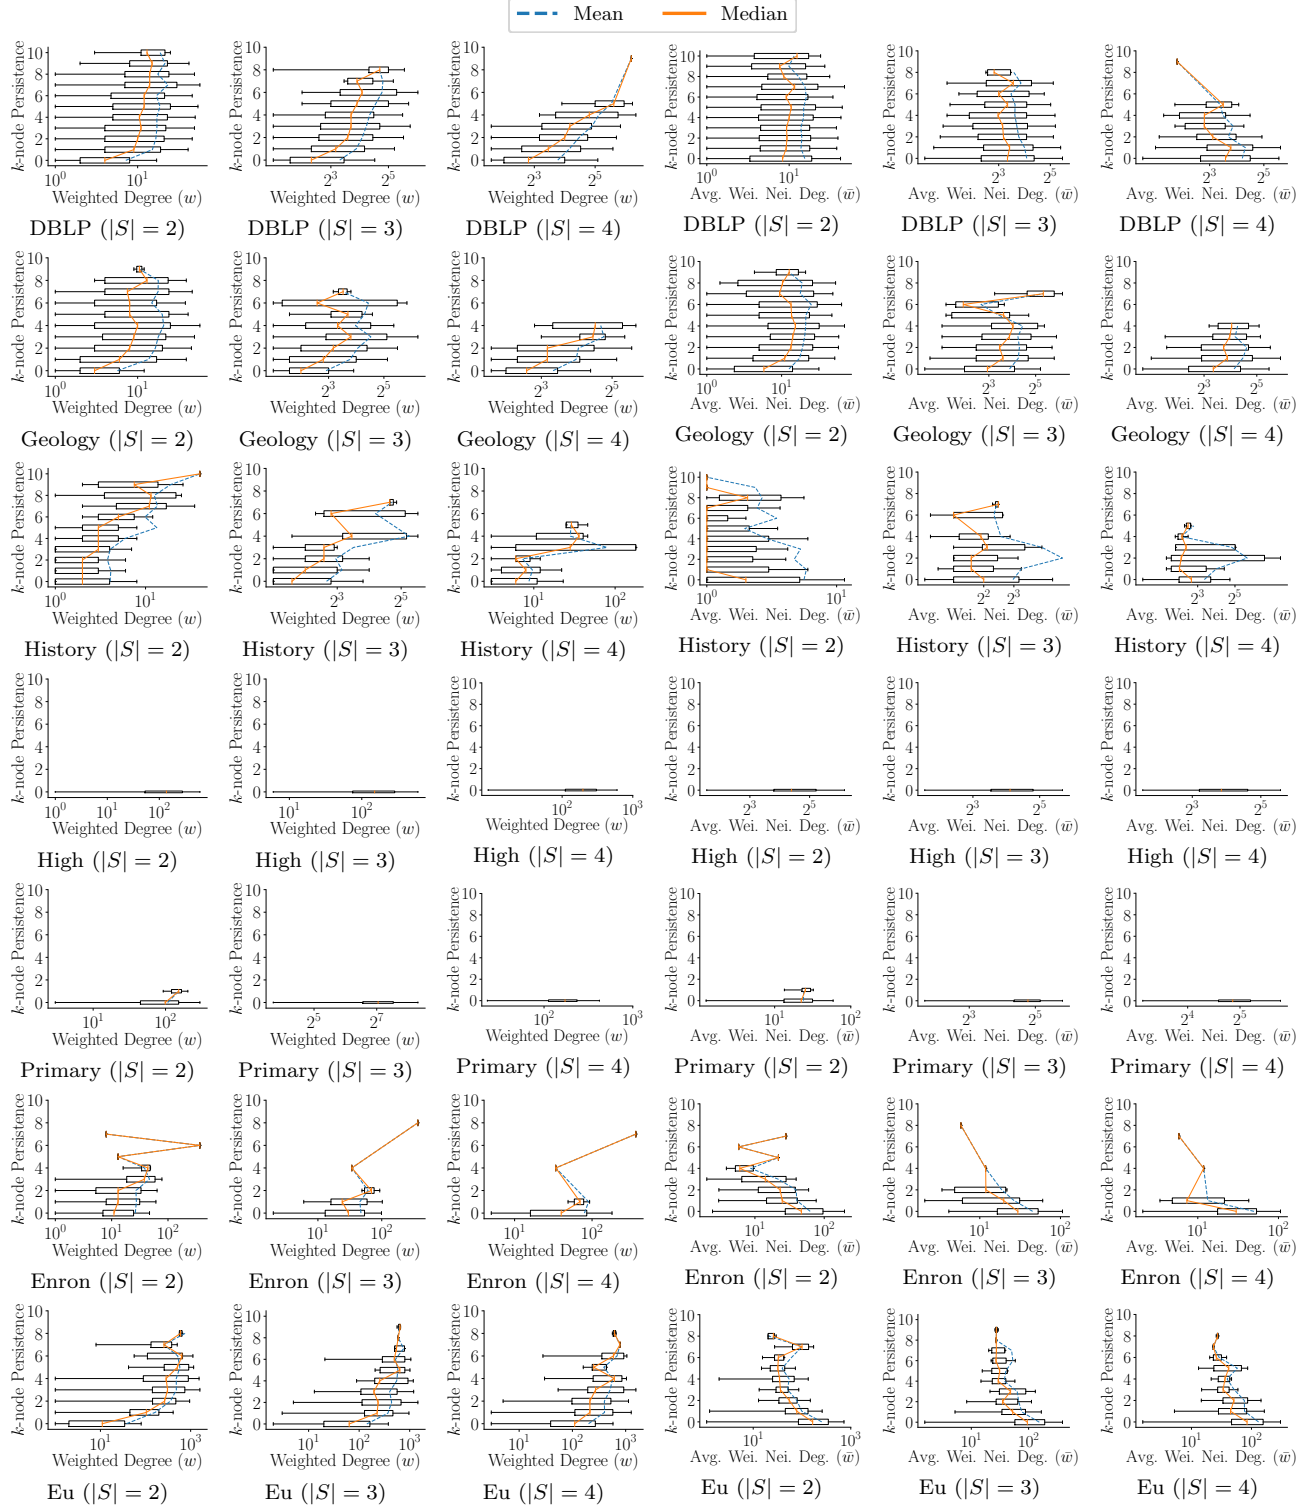

Figure 3: **Node Features vs. Group Persistence.** The distribution of averaged  $w$  (i.e., weighted degree) and  $\bar{w}$  (i.e., the average weighted degree of neighbors) of HOIs with each level of persistence in all 13 real-world hypergraphs.

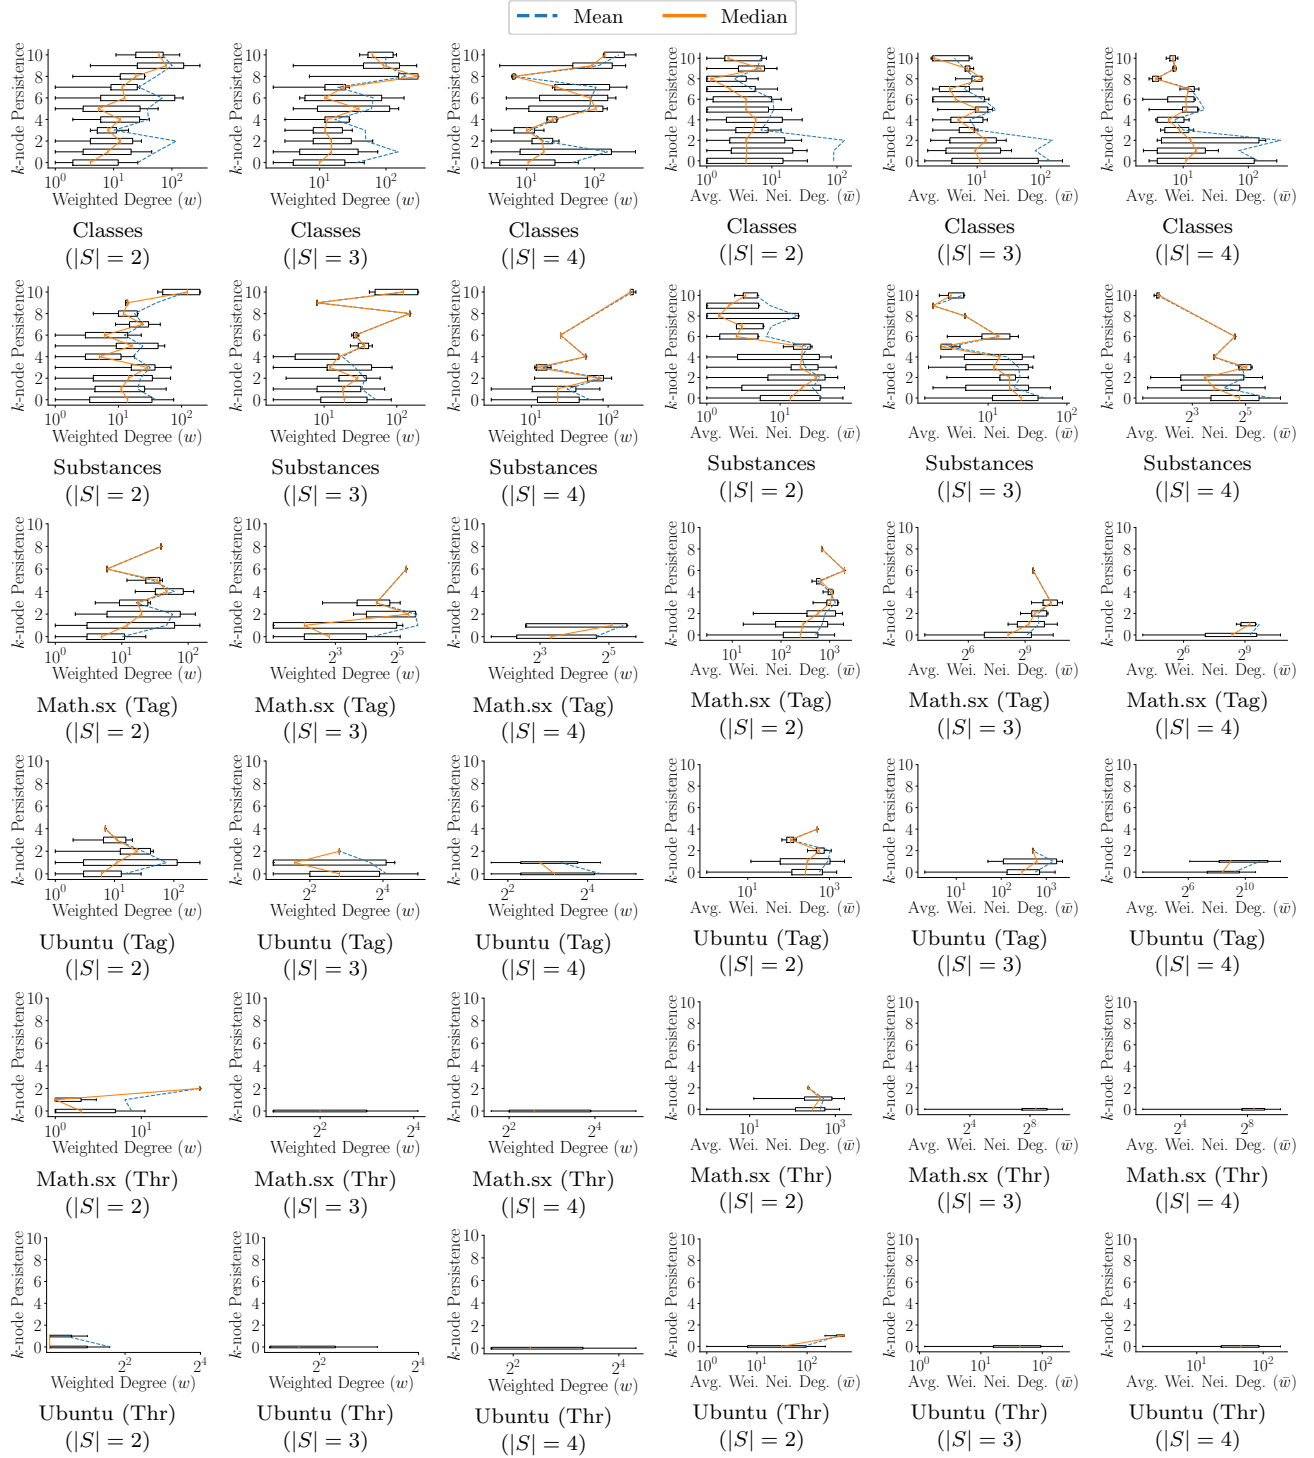

Figure 4: **Node Features vs. Node Persistence.** The distribution of  $w$  (i.e., weighted degree) and  $\bar{w}$  (i.e., the average weighted degree of neighbors) of nodes with each level of  $k$ -node persistence in all 13 real-world hypergraphs.

Table 2: The average coefficient, standard error, and  $p$ -value of each structural feature obtained by linear regression analysis of each dataset.

Table 3: **Statistical significance of structural features.** We report the number of datasets where each feature is significant with a given  $p$ -value in linear regression analysis.
